

DREAM*

towards high-resolution jet spectroscopy

Richard Wigmans
(Texas Tech University)

Fermilab, 11/11/11 at 11am

Outline:

- (Limitations of) calorimeter measurements in particle physics
- Dual-readout calorimetry
- Recent R&D results (DREAM = RD52)
- Future plans
- Conclusions

* *DREAM (RD52) Collaboration:*

Cagliari, Cosenza, Pavia, Pisa, Roma, Iowa State, TTU

Why calorimetry?

- Measure *charged + neutral* particles
- Obtain information on *energy flow*:
Total (missing) transverse energy, jets, *etc.*
- Obtain information *fast*
→ recognize and select interesting events in real time (*trigger*)
- Performance of calorimeters *improves with energy*
($\sim E^{-1/2}$ if statistical processes are the limiting factor)

If $E \propto \text{signal}$, i.e. $E \propto \# \text{ signal quanta } n \rightarrow \sigma(E) \propto \sqrt{n}$
→ energy resolution $\frac{\sigma(E)}{E} \propto 1/\sqrt{n} \propto 1/\sqrt{E}$

In an ideal calorimeter, resolution scales as $E^{-1/2}$

Important calorimeter features

- Energy resolution
- Position resolution (need 4-vectors for physics)
- Signal speed
- Particle ID capability

The importance of good energy resolution (1)

Particle identification with calorimeters

Using shower profile
(pre-shower detector)

Using time structure
of the signals

Whereas electromagnetic calorimeters (intended for e, γ detection) are typically very precise and very well understood instruments

Hadron calorimeters are usually far from ideal

Energy resolution of a homogeneous hadron calorimeter (60 tonnes of liquid scintillator)

From: NIM 125 (1975) 447

Hadron calorimetry in practice

Energy resolution for a non-compensating calorimeter

FIG. 7.50. Two-jet invariant mass distributions from the UA2 experiment [Alit 91]. Diagram *a)* shows the measured data points, together with the results of the best fits to the QCD background alone (*dashed curve*), or including the sum of two Gaussian functions describing $W, Z \rightarrow q\bar{q}$ decays. Diagram *b)* shows the same data after subtracting the QCD background. The data are compatible with peaks at $m_W = 80$ GeV and $m_Z = 90$ GeV. The measured width of the bump, or rather the standard deviation of the mass distribution, was 8 GeV, of which 5 GeV could be attributed to non-ideal calorimeter performance [Jen 88].

The physics of hadronic shower development

- A hadronic shower consists of two components

- **Electromagnetic component**

- electrons, photons
- neutral pions $\rightarrow 2 \gamma$

- **Hadronic (non-em) component**

- charged hadrons π^\pm, K^\pm (20%)
- nuclear fragments, p (25%)
- neutrons, soft γ 's (15%)
- break-up of nuclei ("invisible") (40%)

- Important characteristics for hadron calorimetry:

- Large, non-Gaussian fluctuations in energy sharing em/non-em
- Large, non-Gaussian fluctuations in "invisible" energy losses

*The calorimeter response to the two shower components
is NOT the same*

(mainly because of nuclear breakup energy losses in non- π^0 component)

(Fluctuations in) the electromagnetic shower fraction, f_{em}
i.e. the fraction of the shower energy deposited by π^0 s

The em fraction is, on average,
large and energy dependent

Fluctuations in f_{em} are
large and non-Poissonian

Fluctuations in the em shower component (f_{em})

- *Why are these important ?*
 - Electromagnetic calorimeter response \neq non-em response ($e/h \neq 1$)
 - Event-to-event fluctuations are large and *non-Gaussian*
 - $\langle f_{em} \rangle$ *depends on* shower *energy* and *age*
- *Cause of all common problems in hadron calorimeters*
 - *Energy scale* different from electrons, in energy-dependent way
 - Hadronic *non-linearity*
 - *Non-Gaussian* response function
 - Poor energy *resolution*
 - *Calibration* of the sections of a longitudinally segmented detector

Hadronic shower profiles: Fluctuations!

π^0 production may take place anywhere in the absorber

FIG. 2.35. Longitudinal profiles for 4 different showers induced by 270 GeV pions in a lead/iron/plastic-scintillator calorimeter. Data from [Gre 94].

Consequences for LHC calorimeters

Hadronic response and signal linearity (CMS)

CMS pays a price for its focus on em energy resolution
ECAL has $e/h = 2.4$, while HCAL has $e/h = 1.3$

→ Response depends strongly on starting point shower

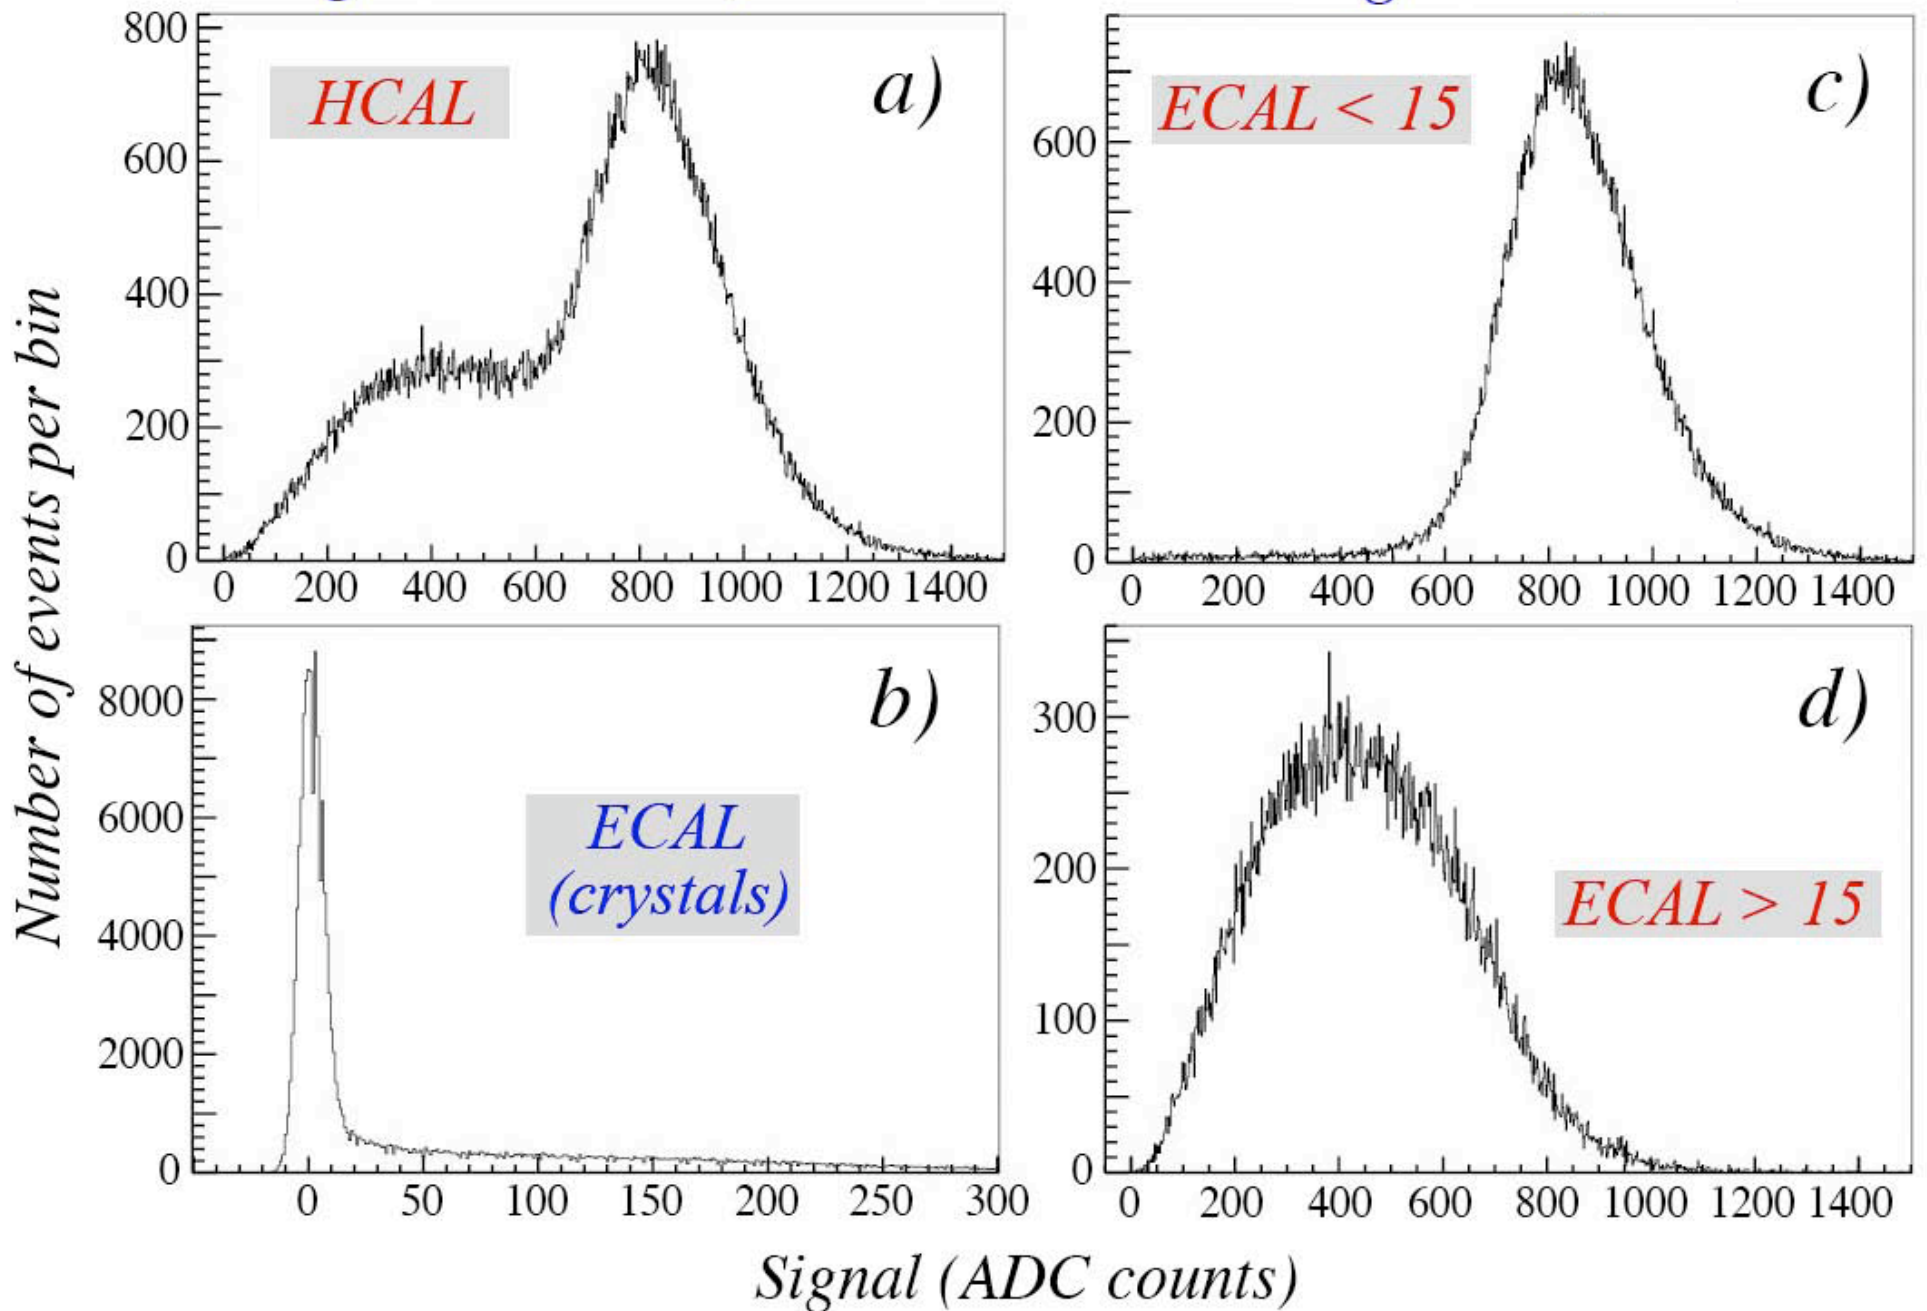

Data from: CMS note 2007/012

Pion signals in crystal ECAL + scintillator HCAL

Signals HCAL, ECAL

Signal HCAL

The future of calorimetry

- *Hadronic calorimetry will become increasingly important, especially if a machine such as CLIC will ever be built. Jet spectroscopy will replace particle spectroscopy, e.g. to distinguish final-state W/Z bosons*
- *Different approaches are followed to develop calorimeter systems that are up to that task:*
 - *Compensating calorimeters*
Proven technology, current holders of all performance records
 - *Dual-readout calorimeters*
Try to improve on the performance of compensating calorimeters by eliminating the weak points of the latter
Many experimental successes have been achieved, goals within reach
 - *Systems based on Particle Flow Analysis*
Combine the information from a tracking system and a fine-grained calorimeter

Compensating calorimetry

- *Reasons for poor hadronic performance of non-compensating calorimeters understood*
- *Compensation mechanisms fully understood*
 - ^{238}U absorber (fission \rightarrow compensation for invisible energy loss) is neither needed nor sufficient*
 - Experimentally demonstrated with Pb/scintillator calorimeters (ZEUS, SPACAL)*

Hadronic signal distributions in a compensating calorimeter

from: NIM A308 (1991) 481

SPACAL 1989

Hadron calorimetry in practice

Energy resolution in a compensating calorimeter

W/Z separation:

$$\frac{\Delta m}{m} \sim 0.11$$

The WA80 calorimeter as high-resolution spectrometer.
Total energy measured with the calorimeter for minimum-bias events revealed the composition of the momentum-selected CERN heavy-ion beam

Pros & Cons of Compensating Calorimeters

Pros

- Same *energy scale* for electrons, hadrons and jets. No ifs, ands or buts.
- *Calibrate* with electrons and you are done.
- Excellent hadronic *energy resolution* (SPACAL: $30\%/\sqrt{E}$).
- *Linearity*, Gaussian *response function* and all that good stuff.
- Compensation fully understood.
We know how to build these things, even though GEANT doesn't

Cons

- Small sampling fraction (2.4% in Pb/plastic)
→ *em energy resolution limited* (SPACAL: $13\%/\sqrt{E}$, ZEUS: $18\%/\sqrt{E}$)
- Compensation relies on detecting neutrons
→ Large *integration volume*
→ Long *integration time* (~ 50 ns)

Elements needed to improve the excellent ZEUS/SPACAL performance:

- 1) *Reduce the contribution of sampling fluctuations to energy resolution
(THE limiting factor in SPACAL/ZEUS)*
- 2) *Eliminate/reduce effects of fluctuations in “invisible energy”
→ calorimeter needs to be efficient in detecting the “nuclear” fraction
of the non-em shower component*
- 3) *Eliminate the effects of fluctuations in the em shower fraction, f_{em}
in a way that does NOT prevent 1), 2)*

→ *Dual-Readout Calorimetry*

An attractive option for improving the quality of hadron calorimetry:

Use Čerenkov light!! Why?

Hadron showers $\left\{ \begin{array}{l} \text{em component } (\pi^0) \\ \text{non-em component (mainly soft } p) \end{array} \right.$

Calorimeter response to these components not the same ($e/h \neq 1$)

Čerenkov light almost exclusively produced by em component
(~80% of non-em energy deposited by non-relativistic particles)

→ DREAM (Dual REAdout Method) principle:

Measure f_{em} event by event by comparing Č and dE/dx signals

DREAM: Structure

- *Some characteristics of the DREAM detector*

- **Depth** 200 cm ($10.0 \lambda_{\text{int}}$)
- Effective **radius** 16.2 cm ($0.81 \lambda_{\text{int}}$, $8.0 \rho_M$)
- **Mass** instrumented volume 1030 kg
- Number of **fibers** 35910, diameter 0.8 mm, total length ≈ 90 km
- Hexagonal **towers** (19), each read out by 2 PMTs

DREAM readout

DREAM: How to determine f_{em} and E ?

$$S = E \left[f_{em} + \frac{1}{(e/h)_S} (1 - f_{em}) \right]$$

$$Q = E \left[f_{em} + \frac{1}{(e/h)_Q} (1 - f_{em}) \right]$$

e.g. If $e/h = 1.3$ (S), 4.7 (Q)

$$\frac{Q}{S} = \frac{f_{em} + 0.21 (1 - f_{em})}{f_{em} + 0.77 (1 - f_{em})}$$

$$E = \frac{S - \chi Q}{1 - \chi}$$

with $\chi = \frac{1 - (h/e)_S}{1 - (h/e)_Q} \sim 0.3$

DREAM: Effect of corrections (200 GeV "jets")

Effects of Q/S corrections on

hadronic signal linearity and jet resolution

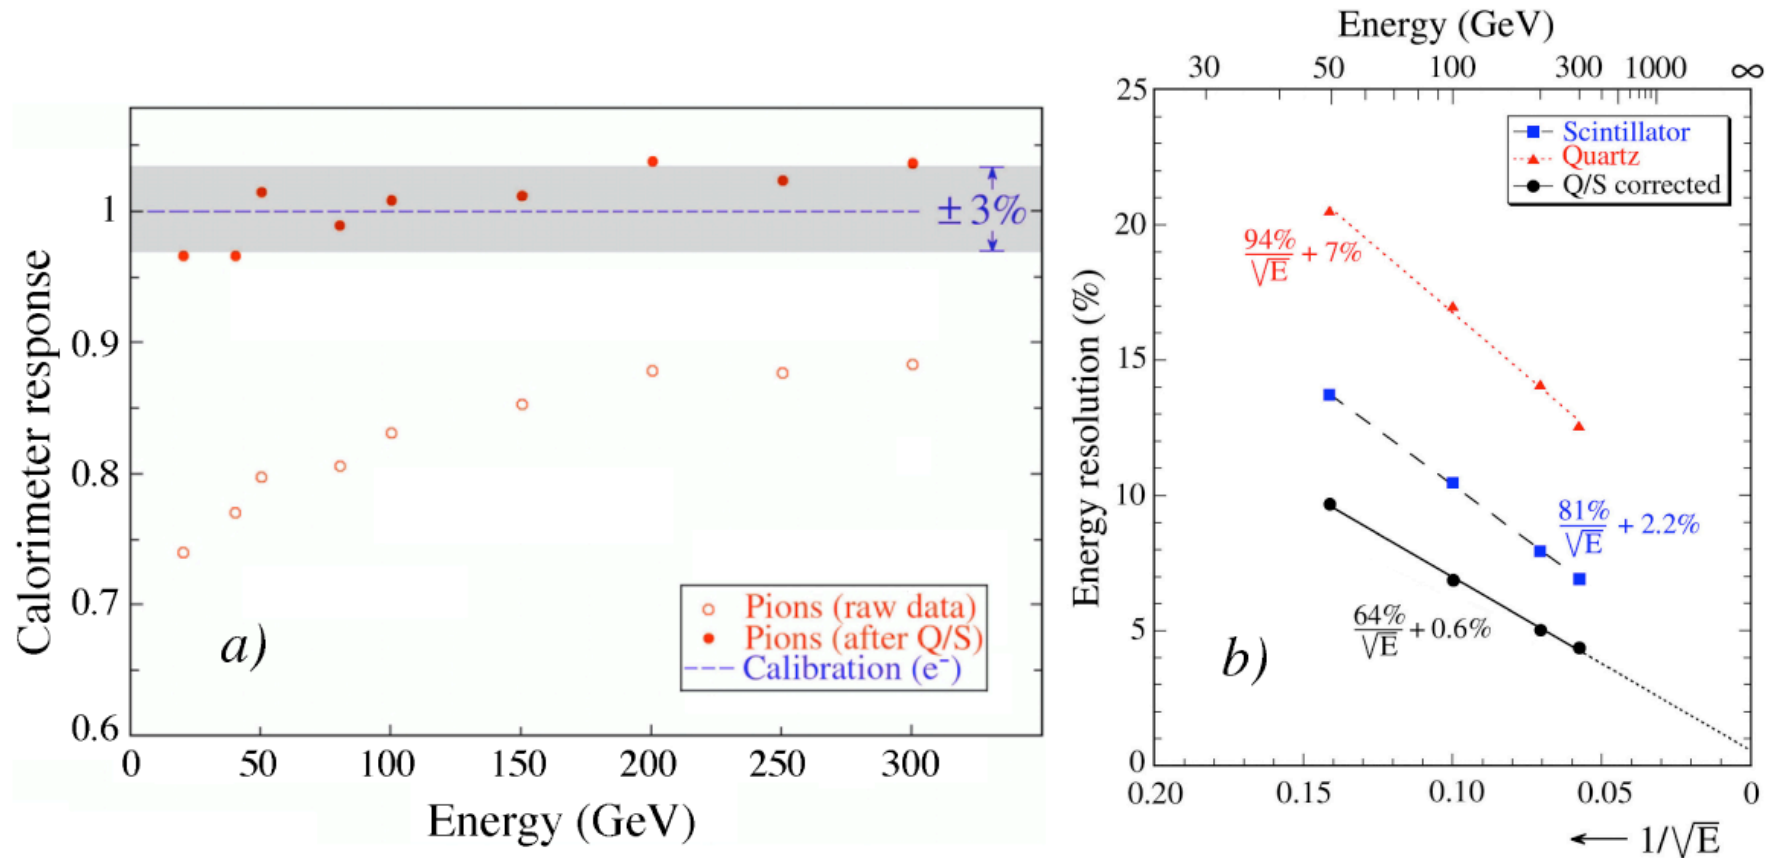

Figure 9: The scintillator response of the DREAM calorimeter to single pions (a) and the energy resolution for “jets” (b), before and after the dual-readout correction procedures were applied to the signals [5].

CONCLUSIONS

from tests of fiber prototype

- **DREAM** offers a powerful technique to *improve* hadronic calorimeter performance:
 - **Correct hadronic energy** reconstruction, *in an instrument calibrated with electrons!*
 - **Linearity** for hadrons and jets
 - **Gaussian** response functions
 - Energy **resolution scales** with $1/\sqrt{E}$
 - $\sigma/E < 5\%$ for high-energy "jets", in a detector with a **mass of only 1 ton!**
dominated by fluctuations in shower leakage

In other words:

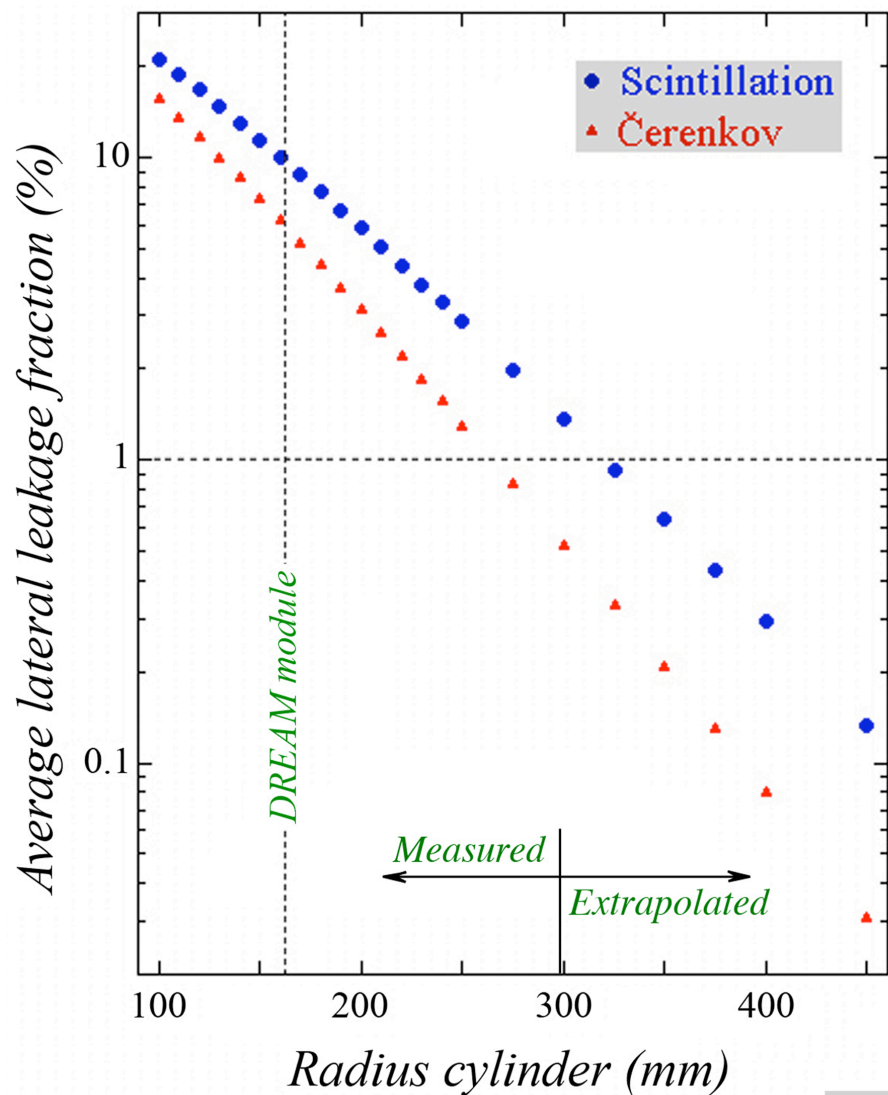

*The same advantages as intrinsically compensating calorimeters ($e/h = 1$)
WITHOUT the limitations (sampling fraction, integration volume, time)*

How to improve DREAM performance

- Build a larger detector → *reduce effects side leakage*

DREAM: The importance of leakage and its fluctuations

Lateral shower containment (π)

From:
NIM A584 (2008) 273

Expected effect of full shower containment

Figure 2: Čerenkov signal distributions for 200 GeV multi-particle events. Shown are the raw data (a), and the signal distributions obtained after application of the corrections based on the measured em shower content, with (c) or without (b) using knowledge about the total “jet” energy [5].

How to improve DREAM performance

- Build a larger detector \longrightarrow *reduce effects side leakage*
- *Increase Čerenkov light yield*
DREAM: 8 p.e./GeV \longrightarrow fluctuations contribute 35%/√E
- *Reduce sampling fluctuations*
These contributed $\sim 40\%/√E$ to hadronic resolution in DREAM

Homogeneous calorimeters (crystals)

- No reason why DREAM principle should be limited to fiber calorimeters
- *Crystals* have the potential to solve light yield + sampling fluctuations problem
- **HOWEVER:** *Need to separate the light into its Č, S components*

OPTIONS:

- 1) **Directionality.** S light is isotropic, Č light directional
- 2) **Time structure.** Č light is prompt, S light has decay constant(s)
- 3) **Spectral characteristics.** Č light λ^{-2} , S light depends on scintillator
- 4) **Polarization.** Č light polarized, S light not.

Separation of $\text{PbWO}_4 : 1\% \text{Mo}$ signals into S, \check{C} components

From:

NIM A604 (2009) 512

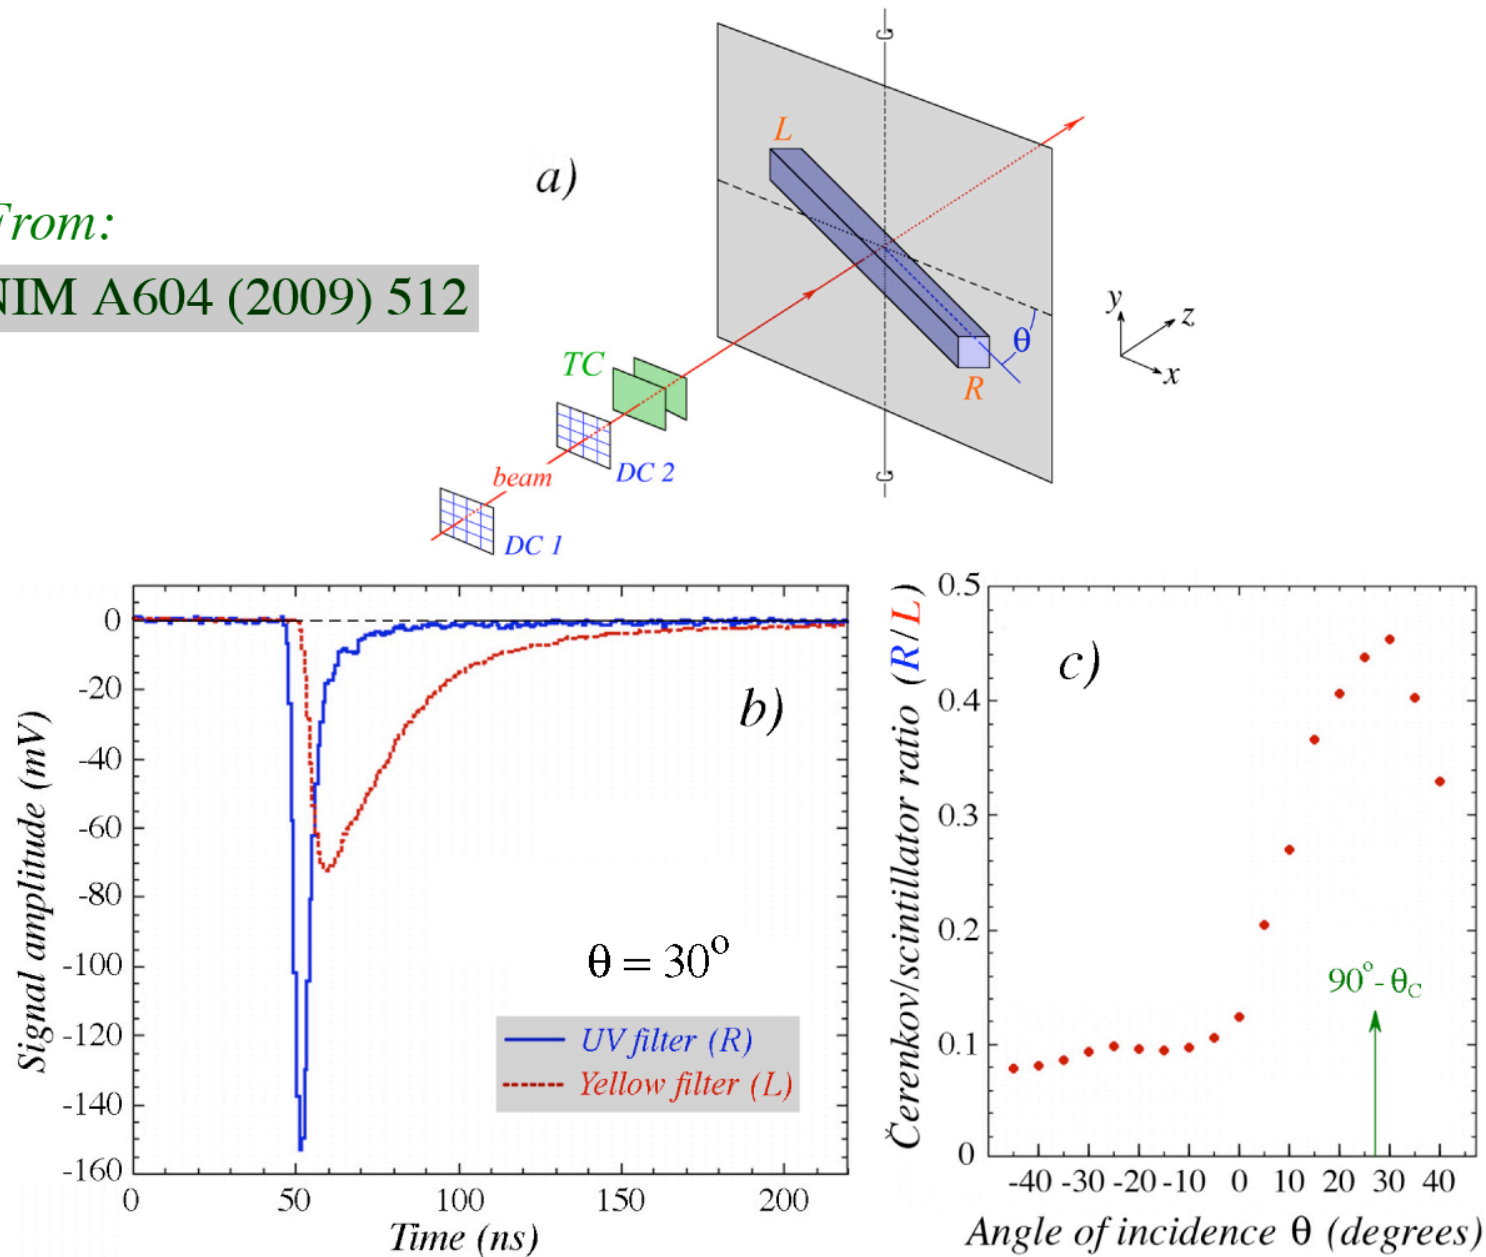

Figure 3: Unraveling of the signals from a **Mo-doped PbWO_4 crystal** into Čerenkov and scintillation components. The experimental setup is shown in diagram *a*. The two sides of the crystal were equipped with a UV filter (side *R*) and a yellow filter (side *L*), respectively. The signals from 50 GeV electrons traversing the crystal are shown in diagram *b*, and the angular dependence of the ratio of these two signals is shown in diagram *c*.

Separating the Čerenkov and scintillation components

electron beam

How to improve DREAM performance

- Build a larger detector \longrightarrow *reduce effects side leakage*
- *Increase Čerenkov light yield*
DREAM: 8 p.e./GeV \longrightarrow fluctuations contribute 35%/√E
- *Reduce sampling fluctuations*
These contributed $\sim 40\%/√E$ to hadronic resolution in DREAM
- For ultimate hadron calorimetry (15%/√E): *Measure E_{kin} (neutrons)*
Is correlated to nuclear binding energy loss (invisible energy)

Can be inferred from the time structure of the signals

Time structure of the DREAM signals: the neutron tail

Probing the total signal distribution with the neutron fraction

From:

NIM A598 (2009) 422

Figure 18: Distribution of the total Čerenkov signal for 200 GeV “jets” and the distributions for three subsets of events selected on the basis of the fractional contribution of neutrons to the scintillator signal.

Neutron information is complementary to f_{em}

Future research plans

We have now reached the point where we believe that we have all the ingredients in hand to build the perfect calorimeter system, or at least a calorimeter system that meets and exceeds the performance requirements of experiments at the ILC and CLIC. We propose to prove this statement by building and testing such a detector.

(from proposal to funding agencies)

Crucial aspects of proposal

- Concentrate on fiber calorimetry.
 - *Shower containment >99%, i.e. mass ~ 5 tonnes*
→ *effects of leakage fluctuations negligible*
 - *Preferably copper absorber*
- Other design criteria:
 - *Čerenkov light yield in fiber detector > 100 p.e./GeV (em)*
 - *Sampling fluctuations fiber detector < 10%/√E (em)*
 - *Depth measurement of shower maximum for each event (attenuation!)*
 - *Time structure measured for every signal*

Fiber calorimeters vs crystals (1)

Elements needed for high-resolution calorimetry:

- *Elimination of contributions of fluctuations in em shower fraction*
Intrinsic compensation ($e/h = 1$) or dual-readout
- *Minimization of contributions of fluctuations in visible energy*
Efficient detection of “nuclear” shower component
(e.g., energy resolution ZEUS much better than D0)
- *Limit contribution of stochastic fluctuations*
These are THE limiting factor for em energy resolution

Fiber calorimeters vs crystals (2)

Advantages crystals:

- No sampling fluctuations*
- Some calibration problems characteristic for sampling calorimeters don't play a role*

Disadvantages crystals:

- No sensitivity to neutrons, and thus to invisible energy fluctuations*
- Light attenuation (also very important!)*
- Readout*
- COST*

Absorber choice: Cu vs Pb

- *Detector mass: $\lambda_{\text{Cu}} = 15.1 \text{ cm}$, $\lambda_{\text{Pb}} = 17.0 \text{ cm}$
Mass $1\lambda^3$: Cu/Pb = 0.35*
- *$e/mip \rightarrow$ Čerenkov light yield Cu/Pb ~ 1.4
(Showers inefficiently sampled in calorimeters with high-Z absorber)*
- *Non-linearity at low energy in calorimeters with high-Z absorber*
Important for jet detection

Time structure signals

Fiber calorimeter: needed for

- precision measurement of start time signals*
- neutron tail of S signals*

Crystals: needed to separate C and S signals

*We use a data acquisition system based on the **DRS** chip*
(Domino Ring Sampler) developed at PSI.*

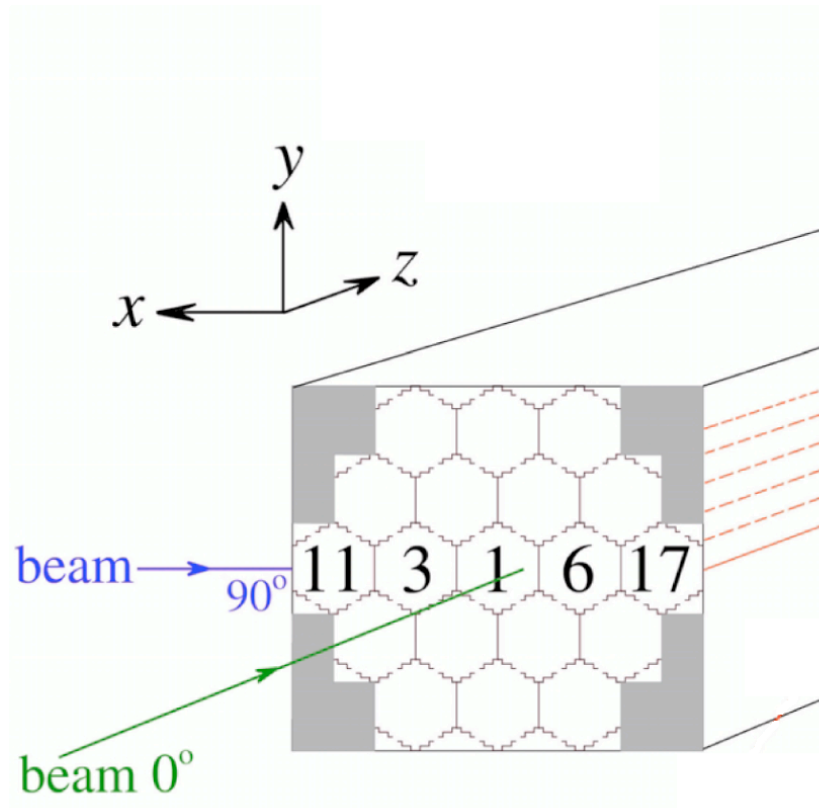

*An array of 1024 switching capacitors samples the input signal,
at a frequency of 5 GHz (DRS-IV).*

Read out by pipeline 12-bit ADC.

** See NIM A518 (2004) 407*

Light attenuation

Experimental setup for DREAM beam tests

$\theta = 2^\circ$: The deeper the light is produced, the more the center-of-gravity of the shower shifts to Tower 6

$$z = \frac{x_{\text{hod}} - x_{\text{cal}}}{\sin \theta}$$

Importance of measuring the depth of the shower maximum event by event

Figure 26: Distribution of the average depth at which the scintillation light is produced in the DREAM calorimeter by showering hadrons (a). Scatter plot showing the total scintillator signal versus the average depth of the light production (a) and the average size of the total scintillator signal as a function of that depth (b), for events induced by 100 GeV π^- mesons. [5].

An alternative method to measure shower depth

Disadvantages of described method:

- *Does not work for neutral particles*
- *Does not work for jets*
- *Non-projective calorimeter impractical*

Alternative makes use of the fact that light in fibers travels at $v = c/n$, while particles producing the light travel at $v \sim c$

*Depth of the light production
and the starting point of the PMT signals*

Conclusions (R&D)

- The DREAM approach combines the advantages of compensating calorimetry with a reasonable amount of design flexibility
- The dominating factors that limited the hadronic resolution of compensating calorimeters (ZEUS, SPACAL) to $30 - 35\%/\sqrt{E}$ can be eliminated
- The theoretical resolution limit for hadron calorimeters ($15\%/\sqrt{E}$) seems within reach
- The DREAM project holds the promise of high-quality calorimetry for *all* types of particles, with an instrument that can be calibrated with electrons

Backup slides

Composition of the non-em shower component

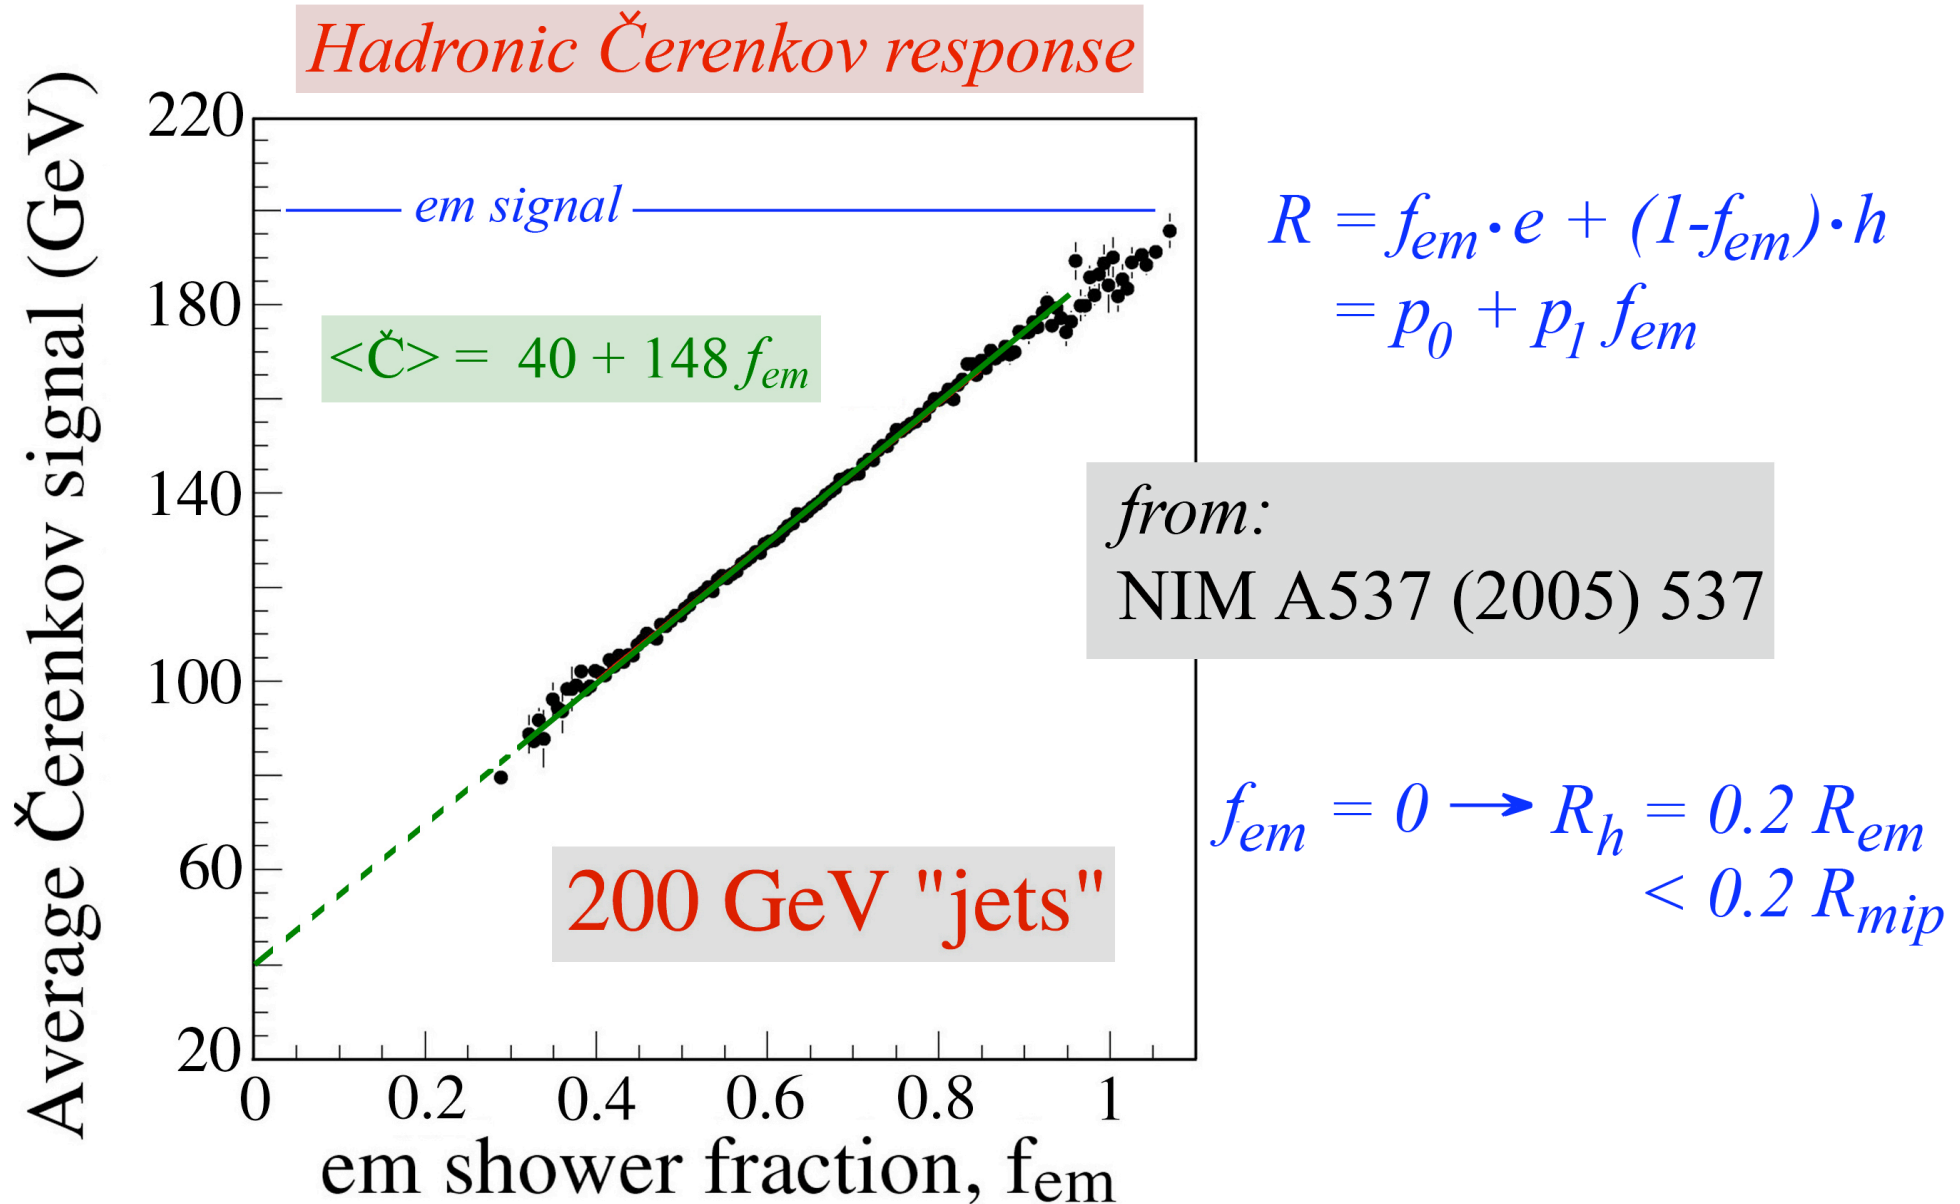

The non-electromagnetic shower component (1)

How do we know that protons dominate (~80%!) of the non-em signals?

1) Because of the small hadronic signals (i.e. large e/h values) of calorimeters that are blind to these protons.

In quartz-fiber calorimeters ($n = 1.46$), only particles with $\beta > 0.69$ emit Čerenkov light, i.e. $E_{kin} > 0.2$ MeV for electrons and > 350 MeV for protons

DREAM: Measure f_{em} event-by-event

The non-electromagnetic shower component (2)

How do we know that protons dominate (~80%!) of the non-em signals?

1) Because of the small hadronic signals (i.e. large e/h values) of calorimeters that are blind to these protons.

In quartz-fiber calorimeters ($n = 1.46$), only particles with $\beta > 0.69$ emit Čerenkov light, i.e. $E_{kin} > 0.2$ MeV for electrons and > 350 MeV for protons

2) Because of the absence of correlations between the signals from adjacent active layers in fine-sampling hadron calorimeters

The calorimeter from the example had $0.06 \lambda_{int}$ thick sampling layers. A mip would lose on average 12.7 MeV traversing these layers.

Correlations between signals from different sampling layers

Fluctuations (%)	10 mm lead / 2.5 mm plastic	
	Electrons	Pions
σ_A, σ_B	36.0 ± 1.0	60.5 ± 1.0
σ_{sum}	24.5 ± 1.0	43.5 ± 1.0
σ_{diff}	25.8 ± 1.0	42.3 ± 1.0

from:
NIM A290 (1990) 335

The crucial elements of hadronic shower simulations (2)

Where do these protons come from?

1) Nuclear spallation.

Spallation protons typically carry ~ 100 MeV kinetic energy.

Their range is typically of the order of the thickness of sampling layers in hadron calorimeters.

2) Nuclear reactions induced by neutrons, e.g. (n,p) reactions

These protons have kinetic energies comparable to those of the (evaporation) neutrons that generated them (< 10 MeV)

These neutrons outnumber spallation protons by an order of magnitude

Measurements of neutron production in hadronic showers:

> 40 per GeV in some materials (NIM A252 (1986) 4)

About the contribution of relativistic hadrons to the signals

$$D. Groom: \langle f_{em} \rangle = 1 - \left[\frac{E}{E_0} \right]^{(k-1)}$$

with E_0 = average shower energy needed for production of 1 secondary π
varies from 0.7 GeV (Fe) - 1.3 GeV (Pb)

$k \sim 0.8$ related to average multiplicity

Example: High-energy hadron on Pb, 100 GeV non-em energy deposit

→ $100/1.3 = 77$ secondary/tertiary shower pions, kaons

- mips in Pb lose 218 MeV per λ_{int} through ionization
→ 77 mips lose in total 16.8 GeV
- π, K may lose a bit more, since λ_{int} defined for protons
- On the other hand, many soft π 's cause Δ resonance production, with cross sections much larger than the asymptotic one used for calculating λ_{int} (e.g. $\pi^+ n \rightarrow p\pi^0$)

→ ionization loss π, K may account for ~20% of non-em E

Naive expectations for hadron calorimeters

Average composition of non-em shower component:

- Pions, kaons,....	20%	(relativistic)
- Protons	25%	
- Neutrons	15%	
- Invisible	40%	

		Exp. value
Cherenkov calorimeter:	$e/h = 1/0.2$	~ 5
Crystal calorimeter:	$e/h = 1/(0.2 + f_1 \cdot 0.25)$ with $f_1 < 1$	> 2
LAr calorimeter:	$e/h = \frac{e}{mip} / (0.2 + f_1 \cdot 0.25)$, $0.6 < \frac{e}{mip} < 1$	$1.3-1.8^*$
Plastic-scint. calorimeter	$e/h = \frac{e}{mip} / (0.2 + f_1 \cdot 0.25 + f_2 \cdot 0.15)$ with $f_2 > 1$	< 1.5

Efficient neutron detection is very important for hadronic energy resolution because kinetic energy neutrons correlated with invisible energy

Compare intrinsic limits SPACAL, ZEUS, D0

* Except for uranium absorbers (fission energy)

Sampling considerations

Sampling fluctuations and the e.m. energy resolution

Figure 23: The em energy resolution of sampling calorimeters as a function of the parameter $(d/f_{\text{samp}})^{1/2}$, in which d is the thickness of an active sampling layer (e.g. the diameter of a fiber or the thickness of a liquid argon gap), and f_{samp} the sampling fraction for mip [20].

Sampling fluctuations

DREAM fiber module: $21\%/√E$ (em), twice as large for hadrons

Decrease the sampling fluctuations as follows:

- Embed fibers individually in metal structure, instead of bunches*

Reduces to $15\%/√E$

- Increase the overall fiber filling fraction*

(from 22% in original fiber module to 43%. PMTs should fit in “shadow”)

Reduces to $11\%/√E$

Combine C + S signals for em showers: $8\%/√E$

Learn from KLOE and SPACAL!

- interaction length 25 cm
- Moliere radius 2.6 cm
- 10λ deep
- radiation length 2.8 cm

Hamamatsu R8900
pc: 85%!

(Čerenkov) light yield

Čerenkov light yield in fiber calorimeter

In original DREAM module:

8 photoelectrons/GeV for quartz fibers (N.A. = 0.33)

18 photoelectrons/GeV for plastic fibers (N.A. = 0.50)

Increase by:

- Using fibers with larger *numerical aperture* x 2
(multi-clad plastic, NA=0.72)
- Increasing the (Čerenkov) *sampling fraction* x 2
- Using PMTs with a larger *quantum efficiency* x 1.5

Expect to reach > 100 p.e./GeV

Miscellaneous DREAM results

Čerenkov/scintillator ratio also measures f_{em} for jets in hybrid!

*On average,
~50% of the "jet" energy
deposited in BGO matrix*

*from
NIM A610 (2009) 488*

Figure 17: The Čerenkov signal distribution for 200 GeV "jet" events detected in the BGO + fiber calorimeter system (a) together with the distributions for subsets of events selected on the basis of the ratio of the total Čerenkov and scintillation signals in this detector combination (b).
