Abstract for TSAPS 2003

Results for Positron-Acetylene Scattering Using the Distributed Positron Model, THOMAS L. GIBSON, Texas Tech University, and PATRICK J. NICHOLS, University of New Orleans — The Distributed Positron Model (DPM) has been developed as a means to include the correlation/polarization interaction between a slow positron and an atomic or molecular target. This technique is based on a quantum chemistry approach that approximates the effect of virtual positronium formation near the target and automatically reduces to the correct long-range form of the polarization potential far from the target. Further, the codes that implement our DPM method have been written to run on low-cost concurrent computers known as GNU/Linux Beowulf clusters. In this talk we will report integrated and differential cross sections for low-energy positron-acetylene collisions.

TTU

Motivation

Why calculate low-energy positron-molecule collisions?

- Very few measured results available
  - Intense low-energy beams are hard to acheive
- Existing experiments don't agree
- Most theories too parameterized or intractable for larger systems

TTU

Our Theoretical Treatment

- Isolated collision between one target (atom or molecule) and one positron of known kinetic energy
- Only elastic scattering—stay below the energy threshold for electronic excitation of the target or for real positronium formation
- Local, energy-independent interaction potential based on physically-motivated approximations

TTU

Reduction of Scattering Formulation

We "reduce" the problem by expanding the (N+1)-particle ket in a complete set of target and scattering states, viz.

$$|\Psi> = \sum\!\!\!\!\!\!\int_{\gamma} F_\gamma \Phi_\gamma .$$

Using this expansion in the T.I.S.E. and operating on the left with $<\Phi_0|$ eventually leaves the one-particle T.I.S.E. for elastic scattering of the positron

$$\hat{T}_p|F_0> - \frac{k^2}{2}|F_0> = -\hat{V}_{sp}|F_0> .$$

TTU

Interaction Potential

A local approximation to the interaction potential between a colliding positron and the molecular target can be represented as

$$V_{sp}(\vec{r}_p) \;=\; V_{st}(\vec{r}_p) \;+\; V_{pol}(\vec{r}_p),$$

where the static potential is given by,

$$V_{st}(\vec{r}_p) \;=\; \left\langle \Phi_0(\vec{r_i}) \left| \hat{V}_{int} \right| \Phi_0(\vec{r_i}) \right\rangle ,$$

with $\hat{V}_{int}$ representing the Coulomb interactions between the positron and the target and where $V_{pol}(\vec{r}_p)$ is the polarization potential.

TTU

Polarization Potential

The polarization potential is defined as the energy difference

$$V_{pol}(\vec{r}_p) \;=\; E^R(\vec{r}_p) - E^U(\vec{r}_p),$$

where the energy from the relaxed (distorted) target orbitals is

$$E^R(\vec{r}_p) \;=\; \left\langle \Phi^R(\vec{r}_i;\vec{r}_p) \left| \hat{\mathcal{H}}_t + \hat{V}_{int} \right| \Phi^R(\vec{r}_i;\vec{r}_p) \right\rangle_{d\vec{r}_i},$$

and the energy from the unrelaxed (ground state) orbitals is

$$E^U(\vec{r}_p) \;=\; \left\langle \Phi_0^U(\vec{r}_i) \left| \hat{\mathcal{H}}_t + \hat{V}_{int} \right| \Phi_0^U(\vec{r}_i) \right\rangle_{d\vec{r}_i}.$$

In the adiabatic approximation, both $E^U(\vec{r}_p)$ and $E^R(\vec{r}_p)$ are calculated by treating the projectile as an additional "proton" (located at $\vec{r}_p$) and using an LCAO:MO—SCF Quantum Chemistry code to provide variational estimates of these energies.

TTU

Nuclear Attraction Integrals

The distortion of the molecular orbitals is driven by the nuclear attraction integrals that involve the positron as an additional "nucleus" at $\vec{r}_p$.

$$I_{i,j}^{NAI} = \langle \alpha_i(\vec{r}_e) \left| V(\vec{r}_e; \rho_{pos}) \right| \beta_j(\vec{r}_e) \rangle \,,$$

where the interaction V from a distribution of positive charge ρ_{pos} is given as

$$V(\vec{r}_e; \rho_{pos}) = \int d\vec{r}\, \rho_{pos}(\vec{r}) \, \frac{-1}{|\vec{r}_e - \vec{r}|}.$$

For the adiabatic approximation, $\rho_{pos}(\vec{r}) = \delta(\vec{r} - \vec{r}_p)$, which is appropriate for the positive charge distribution in a virtual H atom.

TTU

Virtual Positronium vs Virtual Hydrogen

- Adiabatic approximation is much too attractive in the near-target region
- Use ρ_{pos} more nearly correct for virtual Ps
  - Hence, the name Distributed Positron Approximation (DPM)

TTU

Ps C.O.M. Figure

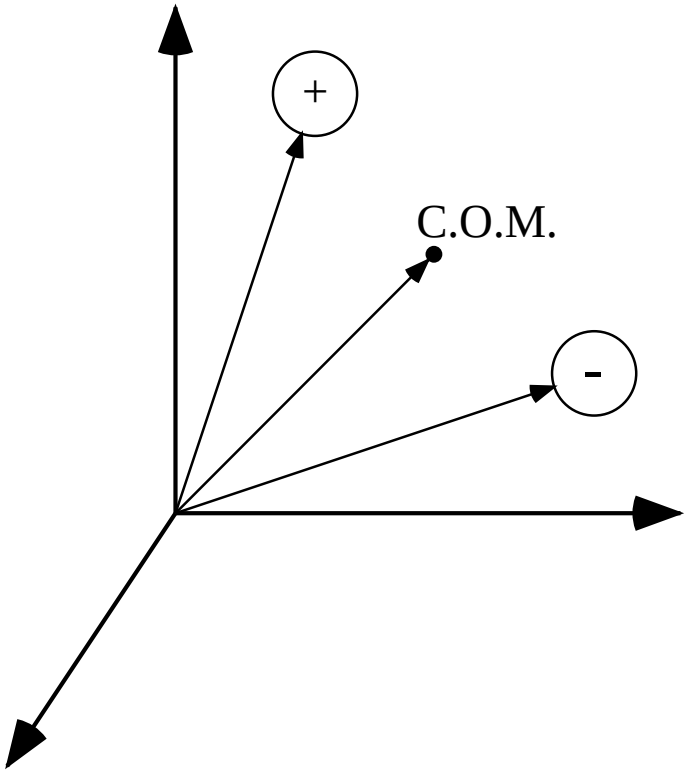

Figure 1: Unlike the H atom, the positive charge in the Ps atom is not localized at the C.O.M. of the atom.

TTU

The Distributed Positron Model

We have investigated several simple choices of ρ_{pos} that reflect the distribution of positive charge in a Ps atom and lead to a polarization potential that reduces to the correct long-range behavior of the polarization potential, including:

- Uniform Spherical
  - R_p = 1.5 Bohr (Average radius of Ps atom)
  - R_p = 1.0 Bohr (Maximum radial probability of Ps atom)
- H1S distribution
- STO-3G distribution

TTU

DPM Figure

For specificity, consider the following case:

- Diatomic target with nuclei at $\vec{A}$ and $\vec{B}$
- Additional "nucleus" (positron) with charge distribution ρ_{pos} located at $\vec{C} \equiv \vec{r}_p$

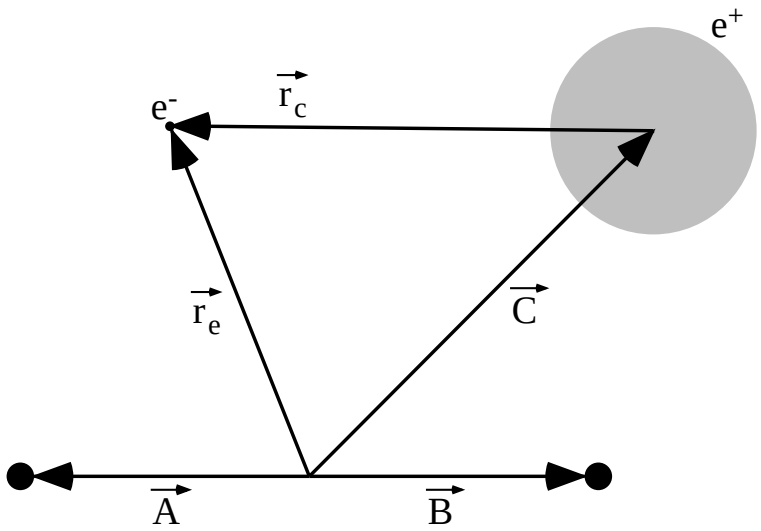

Figure 2: A distribution of positive charge simulates the effect of virtual Ps formation in the DPM.

DPM Distortion Interaction Figure

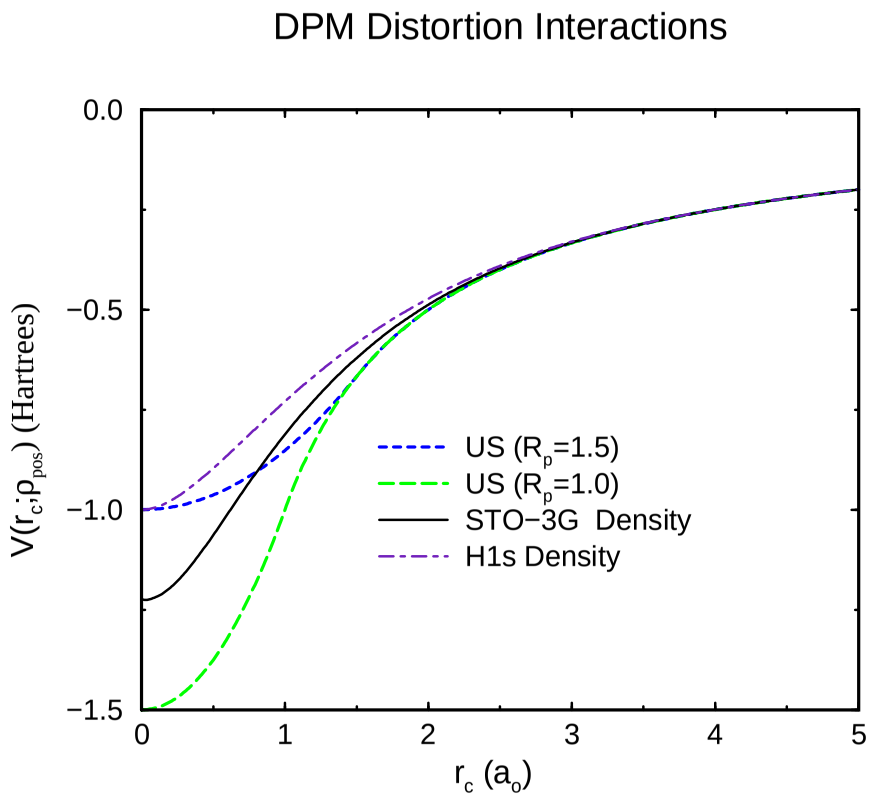

Figure 3: The distortion interaction $V(\vec{r}_c;\rho_{pos})$ for various choices of ρ_{pos} in the DPM.

TTU

Computing the Interaction Potential

To calculate the polarization component of the interaction potential, we fix the positron at a large number of points near the target and then compute a variational estimate of the system energy for each of these points.

- **Bigger Systems $\Longrightarrow$ More CPU Time**
  - Time to compute V_{pol} for Ar: 12 minutes (serial code)
  - Time to compute V_{pol} for SF_6: 125 days (estimated)
- **Bigger Systems $\Longrightarrow$ More Memory**
- **Bigger Systems $\Longrightarrow$ More I/O**

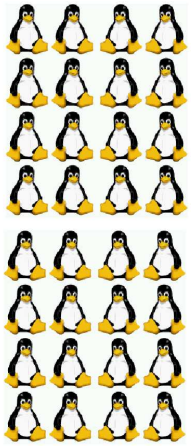
TTU

Solution

- **Beowulf Cluster**
  - Performance: 100's to 1000's of Megaflops
  - Memory: Gigabytes
  - I/O: Distributed Across Multiple Nodes
  - **Very** Affordable Hardware
  - Standard Software Available for Free
  - Local Control
    - Configuration Optimized for Problem
    - No Sharing Required

TTU

Gamera Mark II



TTU

Gamera Mark II Hardware

- 32 1-GHz Athlon CPUs
- 16 Gigabytes aggregate ram
- 640 Gigabytes aggregate disk
- 2 100 base-T 24-port switches
- **Cost** $\sim$ \$30,000

TTU

Conclusions

- High-Performance Computing $\equiv$ Concurrent Computing
- Affordable Parallel Systems Are Available Now
- Open Source Software and Scientific Applications Are Compatible
- The DPM has been shown to yield consistently good agreement with measured low-energy positron-atom and positron-molecule collisions

---

We are grateful for the collaborative efforts of Dr. Robert Lucchese and Dr. Franco Gianturco on the CH_4 and SF_6 systems, as well as our continuing work on C_8H_8.
